# NEW OPPORTUNITIES OPENING UP FOR NIR

## Recent advances in near infra-red (NIR) instruments and technology are creating new opportunities for Australian sugar mills.

One of these next generation NIR instruments – called a Micro NIR – fits into the palm of your hand and costs about one third of the price of its predecessor instruments.

This advance in instrumentation has prompted the Australian industry to investigate the possibilities for NIR analysis in new areas of sugar mills beyond the established applications such as cane payment.

The use of on-line NIR systems, including with support from SRA to analyse and interpret the data, is well-established in a number of Australian mills. The technology allows millers to collect data in real time and also to gather this information in situations where traditional methods are difficult or hazardous.

The smaller instruments that are now available have the potential to fit into new areas of the mill, and their lower capital cost puts the technology within a more realistic cost bracket for new applications.

It is something that Tully Sugar Limited have been keen to further understand. With the help of SRA, they have been testing two Micro NIR instruments attached to the Tully mill in recent seasons.

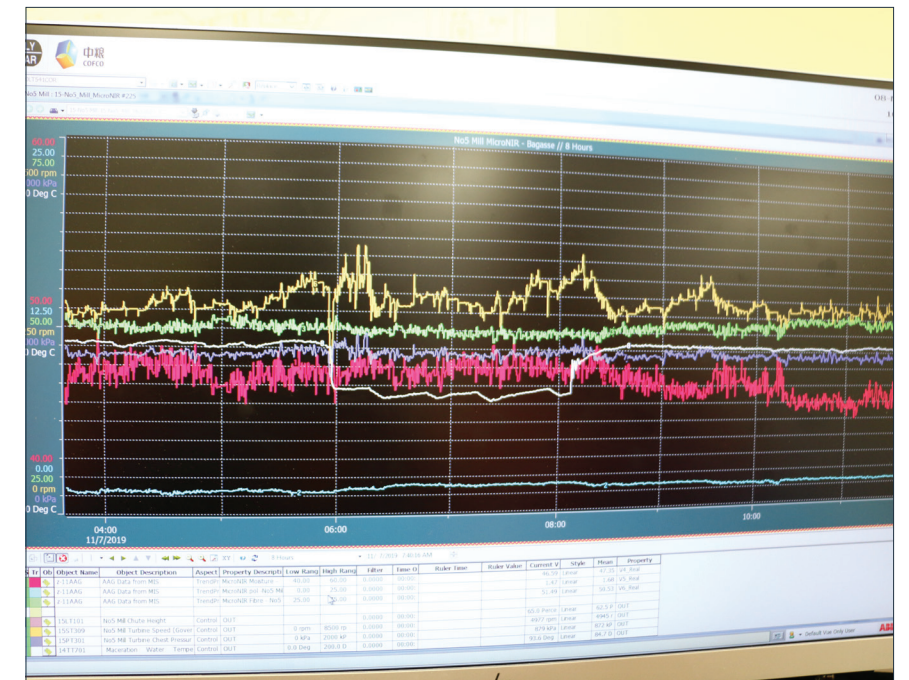

One of these instruments is being used to provide real-time feedback on mill-mud, via an SRA-funded research project. The other instrument is attached to Tully's number five mill and provides real-time and online feedback of bagasse, building on previous research where SRA worked with much larger instruments to assess bagasse at the Mulgrave Mill.

"The real advance now is the instrumentation," SRA's Steve Staunton said. "With the Micro NIR being so compact, it opens up new opportunities. The older systems were also difficult to install and there were challenges around sample presentation and validation.

"With this instrument we are getting information of a similar quality, and it can be done for an investment in the machine of about \$50,000."

SRA provides expertise and support to ensure efficient use of the Micro NIR, and also ensures the data generated by the instrument is accurate and understandable.

TSL Operations Engineer, Ross Threlfall, said TSL was interested in the Micro NIR to see where it could enhance milling efficiency and consistency.

With the bagasse, for example, they were previously only measuring moisture content via moisture meter, whereas now the Micro NIR is providing moisture, pol and fibre every seven seconds.

"Currently bagasse quality analysis is performed by the laboratory, from samples taken over an 8hr shift. These results are only available on a daily basis," Mr Threlfall said. "With online monitoring, control or mill adjustments can be made sooner rather than later to optimise milling extraction.

"Our boiler operators are able to confirm and potentially take action earlier, in response to high moisture bagasse being received at boilers.

"It also gives us the ability to take action such as adjusting the maceration settings, or trying things like cool maceration. We have trialled different maceration settings this year, and we are still learning what we can do with the instrument."

The instrument has been attached directly to the exit chute of the mill and requires cooling due to the temperature of the bagasse (about 85 degrees Celsius or more). This is one of many issues that SRA has worked with TSL on during this season, to better understand how to best use the instrument in the tough environment of a sugar mill. There has also been a huge effort and collaboration with the TSL information technology team and engineering team.

In the future, the Micro NIR and supporting programming may also be able to gather valuable data on the full milling train to

help minimise sugar loss through the mill, especially when used in conjunction with their existing NIR instrument looking at cane at the number one mill.

As they continue to look for new ways to use the data, Mr Threlfall said the Micro NIR would also allow TSL to calculate the calorific value of bagasse, which could then be correlated back to cane variety information. This could be useful for cogeneration by targeting particular bagasse for storage for use in the off-season.

There are other opportunities that are also being considered. This investigation has seen SRA work with TSL engineers and boilermakers to attach a Micro NIR to the mud hopper to determine factors such as pol losses and mud quality criteria.

Mr Staunton said the research could create additional value for growers as it could lead to them being able to better understand the beneficial impacts of recycling mill mud back to their farms.

This data offers advantages to both growers and millers, and may be useful for the industry to continue to demonstrate its strong adherence to best management practices. ■
